

Dynamics, temperature, chemistry, and dust:

Ingredients for a self-consistent AGB wind

Jels Boulangier - KU Leuven

N. Clementel - KU Leuven

D. Gobrecht - KU Leuven

J. Yates - UC London

A. de Koter - KU Leuven/ Uv Amsterdam

A. J. van Marle - UNIST Usan

Sup. **L. Decin** - KU Leuven

The chemical life cycle

B.Saxton NRAO/AUI/NSF

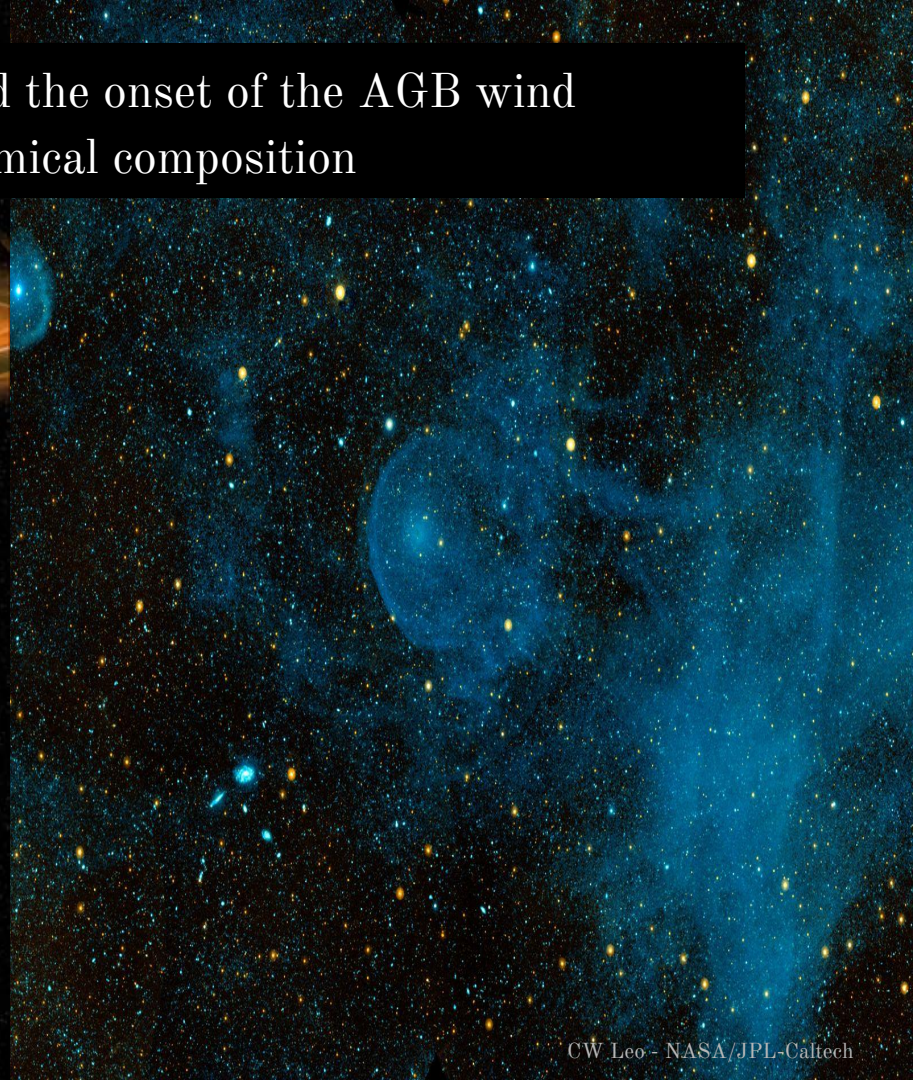

CW Leo - NASA/JPL-Caltech

Understand the onset of the AGB wind and its chemical composition

B.Saxton NRAO/AUI/NSF

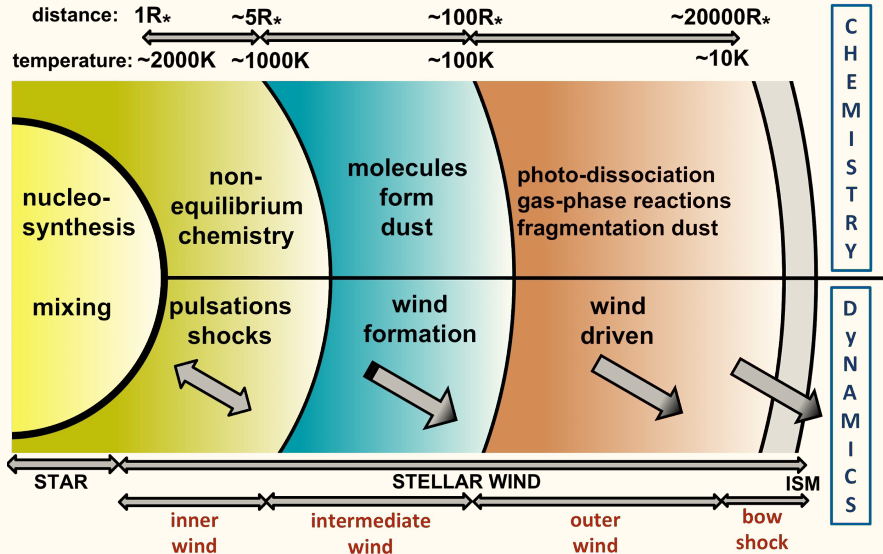

CW Leo - NASA/JPL-Caltech

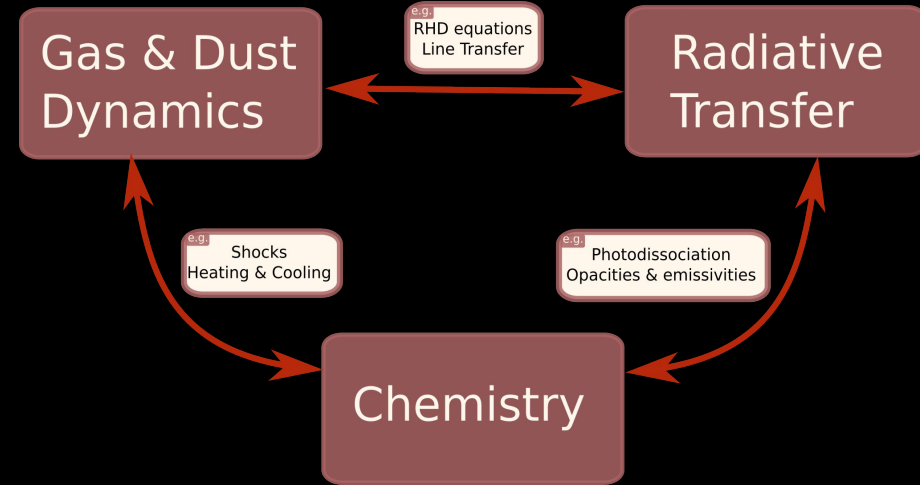

Current limitations

1. Lack of **high resolution** observations
 2. **Simplified** theoretical models
 3. Lack of **laboratory data**
-

Questions

1. What is the **dynamical structure** in AGB winds?
 2. Which **chemical pathways** are most dominant?
 3. How important is the chemical-dynamical **feedback loop**?
 4. Do chemical **instabilities** exist?
 5. What types of **dust** are able to form?
-

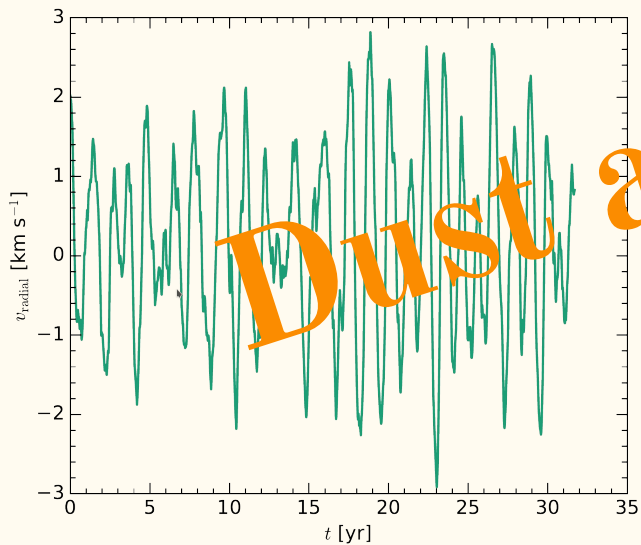

Hydro alone cannot drive the wind

Radial velocity at R_\star from 3D-RHD models (Freitag et al. 2017)

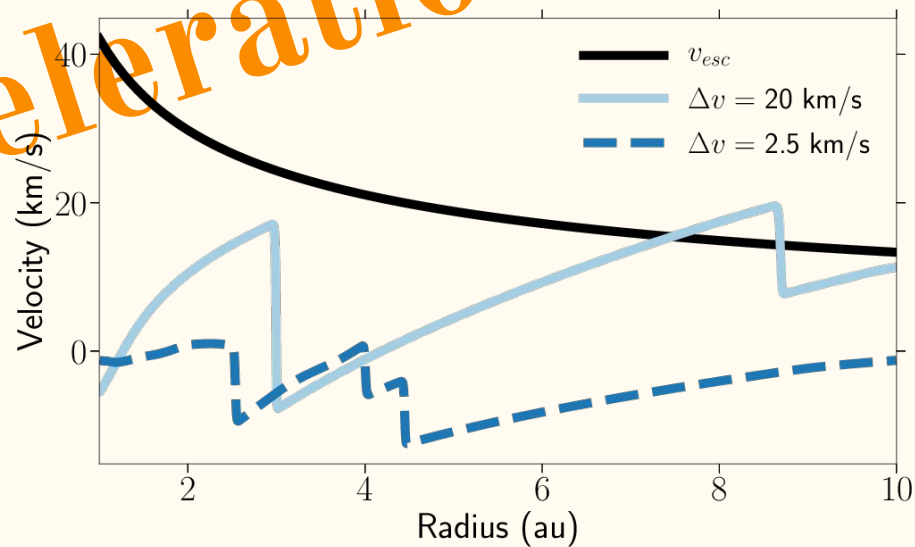

Hydro alone cannot drive the wind

Radial velocity at R_\star from 3D-RHD models (Freitag et al. 2017)

Dust acceleration

Hydro alone cannot drive the wind

Radial velocity at R_\star from 3D-RHD models (Freytag et al. 2017)

Dust acceleration

Too high temperatures

Current chemistry

2 step improvement

Equilibrium

The diagram consists of two rounded rectangular boxes. The left box is outlined in dark red and contains the word 'Equilibrium'. A teal arrow points from the right side of this box to the left side of a larger, empty rounded rectangular box outlined in teal. The teal box is positioned under the text '2 step improvement'.

Current nucleation

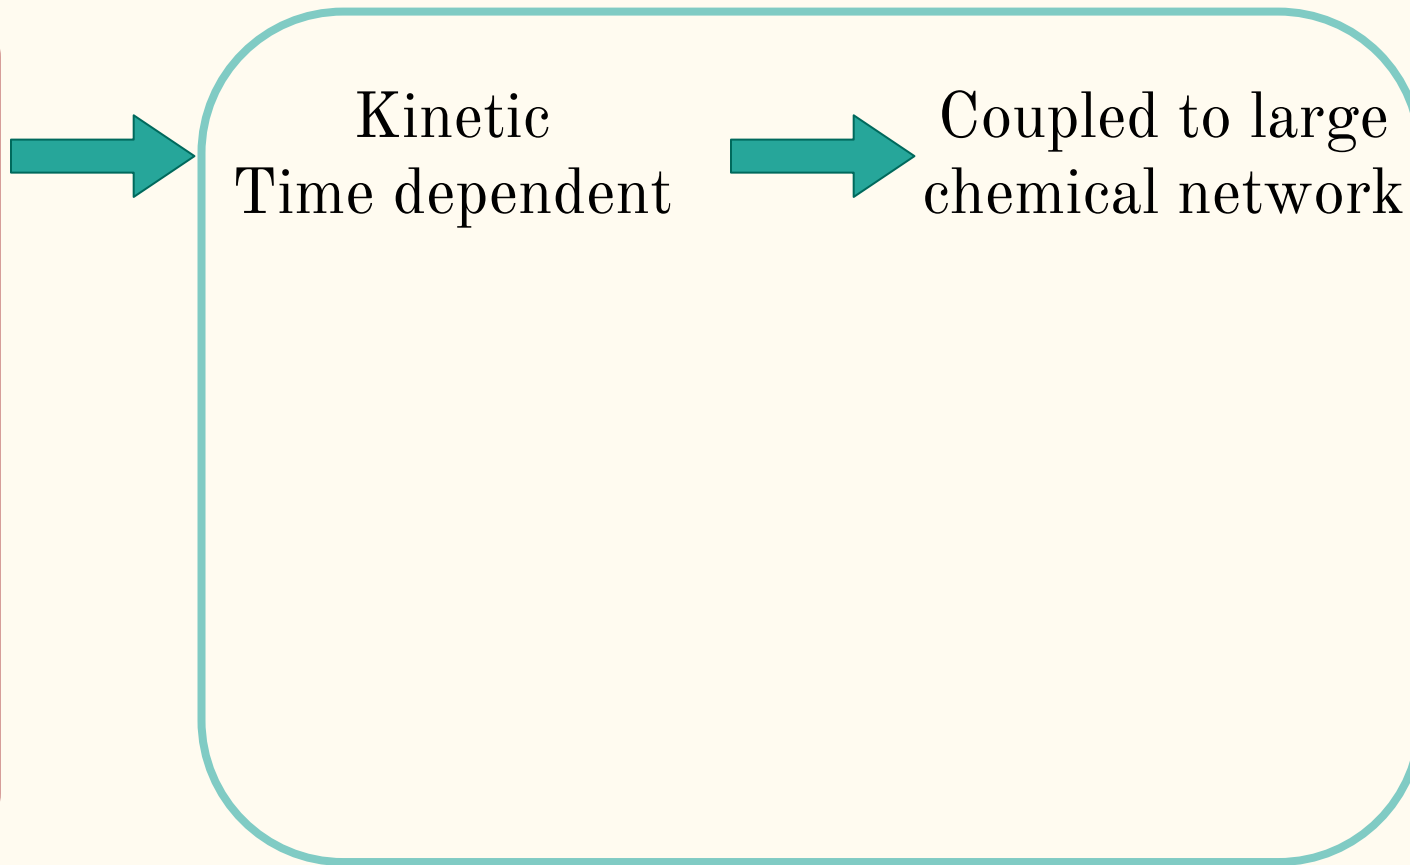

2 step improvement

Different candidates, different temperatures

Absolute $(\text{Al}_2\text{O}_3)_7$ abundance

Absolute $(\text{MgO})_{10}$ abundance

Absolute $(\text{TiO}_2)_{10}$ abundance

Absolute $(\text{SiO}_2)_9$ abundance

Cannot form any Al_2O_3 , Al in other molecules

Bottleneck at $(\text{MgO})_3$

$(\text{MgO})_2$

Mg

$(\text{SiO})_N$ needs too low temperature

$(\text{SiO})_9$

$(\text{SiO})_2$

$(\text{TiO}_2)_N$ is still a good candidate

$(\text{TiO}_2)_{10}$

$(\text{TiO}_2)_{10}$ only $(\text{TiO}_2)_N$ nucleation

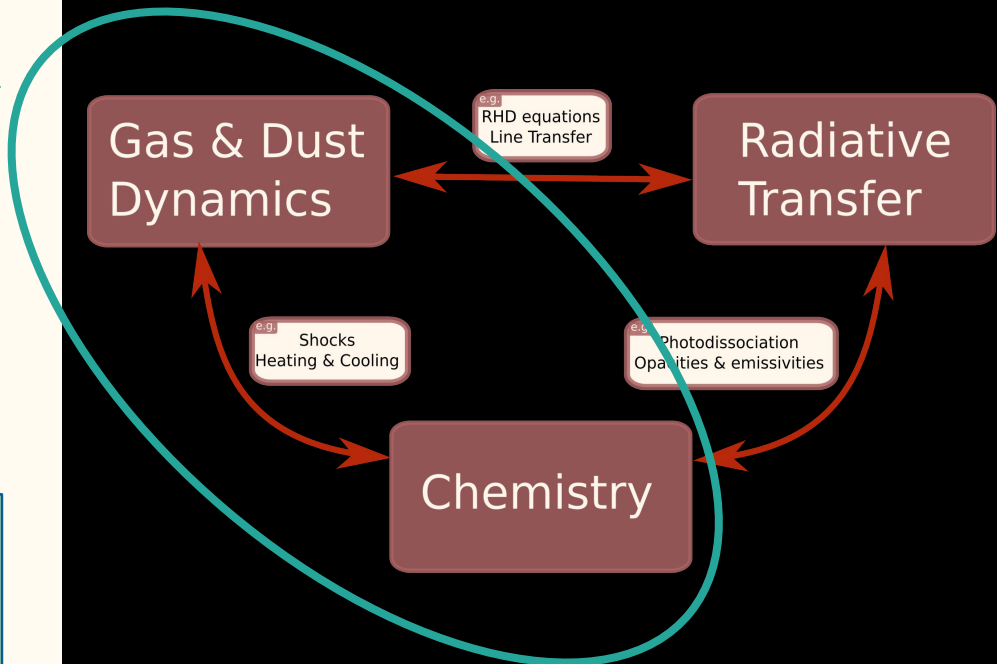

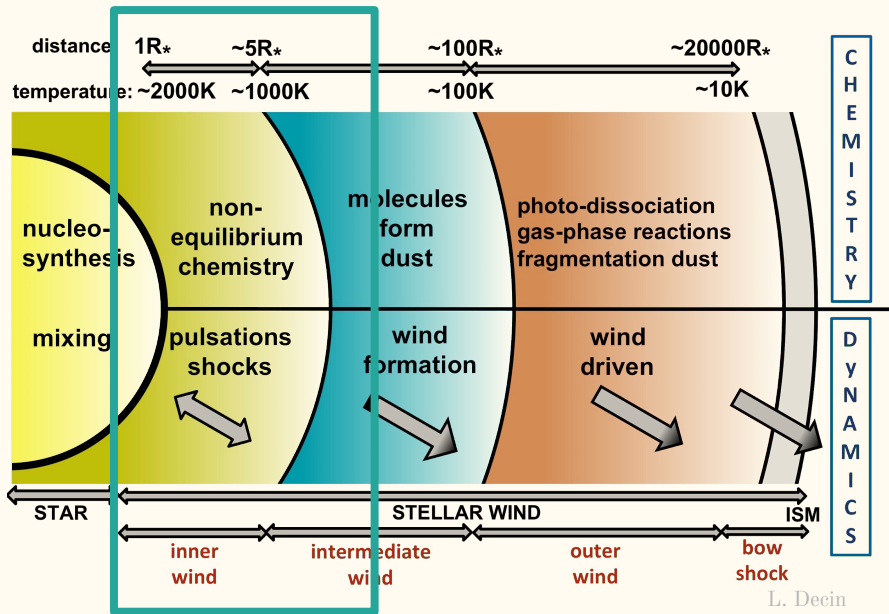

Open questions

- **Missing reactions** to form $(\text{Al}_2\text{O}_3)_N$ clusters?
 - Will there be **enough Ti**?
 - Will $(\text{TiO}_2)_N$ clusters **form fast enough** with low temperature-limit?
 - What if **temperature varies**?
 - Need for **composite clusters**?
-

Self-consistent hydrochemistry

More correct dynamical, temperature and chemical abundance profile

+ Self-consistent nucleation

Removes assumptions on seed particles positions, abundances, and composition

Find important reactions

1. Run chemical network in (temperature, density) - grid
2. Get flux of all reactions at different time steps during the evolution
3. Reaction is important if:

$$\frac{\textit{Flux of reaction}}{\textit{Sum of fluxes of all reactions}}$$

in any given (temperature, density, time) - grid point

> **Threshold**

User defined

Compare abundance of reduced network with original network

Threshold = 10^{-7}

~250 reactions and ~70 species

Speed-up factor ~20

Reduction check example: SiO

Original

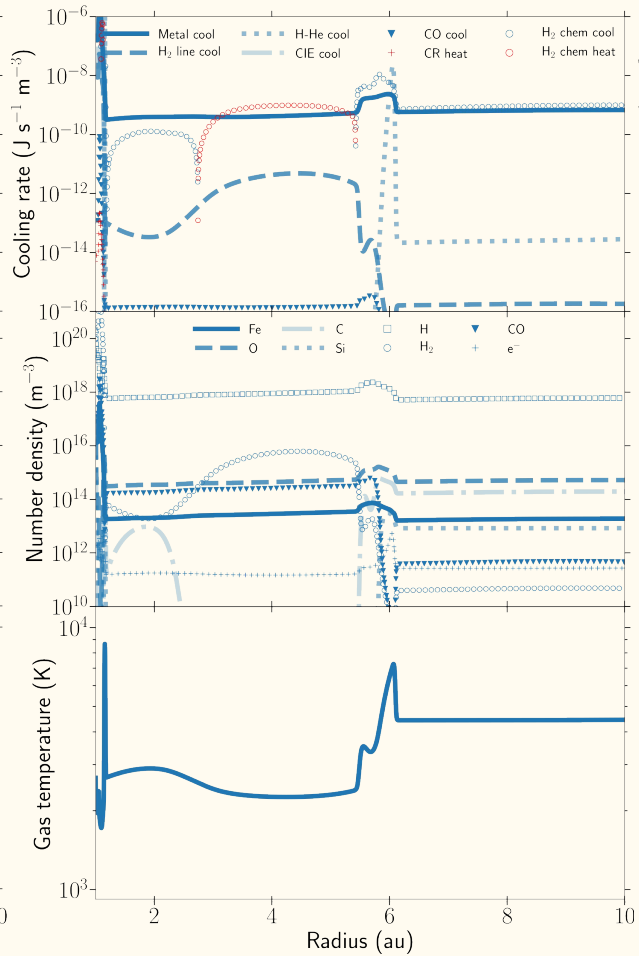

Threshold = 10⁻⁴

Threshold = 10⁻⁷

$t_{\text{hydro}} + 20$ days $t_{\text{hydro}} + 100$ days $t_{\text{hydro}} + 300$ days

(Boulangier et al.
2018a sub.)

Cluster growth/destruction

$$\text{Grow rate} = n_N * n_1 * k^+$$

$$k^+ = P_{\text{meet}} * \cancel{P_{\text{react}}}$$

$$\text{Destruction rate} = n_N * k^-$$

$$k^- \propto k^+ * \exp[-\Delta G_r/kT]$$

Gibbs free energy

(An introduction to thermal physics - D. Schroeder)

Determine minimal energy structure
via density functional theory

Identify internal degrees of freedom
via vibrational analysis

Obtain Gibbs free energy
via thermodynamics

Nucleation candidates

	$(\text{TiO}_2)_N$	$(\text{SiO})_N$	$(\text{MgO})_N$	$(\text{Al}_2\text{O}_3)_N$
N_{max}	10	9	10	7
